Cardinality rationals reals

Comparing \mathbb{Q} and \mathbb{R}

Both \mathbb{Q} and \mathbb{R} have no greatest element.

Both \mathbb{Q} and \mathbb{R} have no least element.

The quantified statement

$$\forall x \forall y (x < y \rightarrow \exists z (x < z < y))$$

is true about both \mathbb{Q} and \mathbb{R} .

Both \mathbb{Q} and \mathbb{R} are infinite. But, \mathbb{Q} is countably infinite whereas \mathbb{R} is uncountable.

The set of real numbers

 $\mathbb{Z}\subsetneq\mathbb{Q}\subsetneq\mathbb{R}$

Order axioms (Rosen Appendix 1):

Reflexivity $\forall a \in \mathbb{R} (a < a)$

Antisymmetry $\forall a \in \mathbb{R} \ \forall b \in \mathbb{R} \ (\ (a \leq b \ \land \ b \leq a) \to (a = b)\)$

Transitivity $\forall a \in \mathbb{R} \ \forall b \in \mathbb{R} \ \forall c \in \mathbb{R} \ (\ (a \leq b \land b \leq c) \ \rightarrow \ (a \leq c) \)$

Trichotomy $\forall a \in \mathbb{R} \ \forall b \in \mathbb{R} \ (\ (a = b \ \lor \ b > a \ \lor \ a < b)$

Completeness axioms (Rosen Appendix 1):

Least upper bound Nested intervals Every nonempty set of real numbers that is bounded above has a least upper bound For each sequence of intervals $[a_n, b_n]$ where, for each n, $a_n < a_{n+1} < b_{n+1} < b_n$, there is at least one real number x such that, for all n, $a_n \le x \le b_n$.

Each real number $r \in \mathbb{R}$ is described by a function to give better and better approximations

$$x_r: \mathbb{Z}^+ \to \{0,1\}$$
 where $x_r(n) = n^{th}$ bit in binary expansion of r

r	Binary expansion	x_r	
0.1	0.00011001	$x_{0.1}(n) = \begin{cases} 0 & \text{if } n > 1 \text{ and } (n \text{ mod } 4) = 2\\ 0 & \text{if } n = 1 \text{ or if } n > 1 \text{ and } (n \text{ mod } 4) = 3\\ 1 & \text{if } n > 1 \text{ and } (n \text{ mod } 4) = 0\\ 1 & \text{if } n > 1 \text{ and } (n \text{ mod } 4) = 1 \end{cases}$	
$\sqrt{2} - 1 = 0.4142135\dots$	0.01101010	Use linear approximations (tangent lines from calculus) to get algorithm for bounding error of successive operations. Define $x_{\sqrt{2}-1}(n)$ to be n^{th} bit in approximation that has error less than $2^{-(n+1)}$.	

Claim: $\{r \in \mathbb{R} \mid 0 \le r \land r \le 1\}$ is uncountable.

Approach 1: Mimic proof that $\mathcal{P}(\mathbb{Z}^+)$ is uncountable.

Proof: By definition of countable, since $\{r \in \mathbb{R} \mid 0 \le r \land r \le 1\}$ is not finite, **to show** is $|\mathbb{N}| \ne |\{r \in \mathbb{R} \mid 0 \le r \land r \le 1\}|$.

To show is $\forall f: \mathbb{Z}^+ \to \{r \in \mathbb{R} \mid 0 \le r \land r \le 1\}$ (f is not a bijection). Towards a proof by universal generalization, consider an arbitrary function $f: \mathbb{Z}^+ \to \{r \in \mathbb{R} \mid 0 \le r \land r \le 1\}$. **To show**: f is not a bijection. It's enough to show that f is not onto. Rewriting using the definition of onto, **to show**:

$$\exists x \in \{r \in \mathbb{R} \mid 0 \le r \land r \le 1\} \ \forall a \in \mathbb{N} \ (f(a) \ne x)$$

In search of a witness, define the following real number by defining its binary expansion

$$d_f = 0.b_1b_2b_3\cdots$$

where $b_i = 1 - b_{ii}$ where b_{jk} is the coefficient of 2^{-k} in the binary expansion of f(j). Since $d_f \neq f(a)$ for any positive integer a, f is not onto.

Approach 2: Nested closed interval property

To show $f: \mathbb{N} \to \{r \in \mathbb{R} \mid 0 \le r \land r \le 1\}$ is not onto. **Strategy**: Build a sequence of nested closed intervals that each avoid some f(n). Then the real number that is in all of the intervals can't be f(n) for any n. Hence, f is not onto.

Consider the function $f: \mathbb{N} \to \{r \in \mathbb{R} \mid 0 \le r \land r \le 1\}$ with $f(n) = \frac{1+\sin(n)}{2}$

$n \mid$	$\int f(n)$	Interval that avoids $f(n)$
0	0.5	
1	0.920735	
2	0.954649	
3	0.570560	
4	0.121599

¹There's a subtle imprecision in this part of the proof as presented, but it can be fixed.

Least greatest proofs

-
For a set of numbers X , how do you formalize "there is a greatest X " or "there is a least X "?
Prove or disprove: There is a least prime number.
Prove or disprove: There is a greatest integer.
Approach 1, De Morgan's and universal generalization:
Approach 2, proof by contradiction:
Extra examples: Prove or disprove that \mathbb{N} , \mathbb{Q} each have a least and a greatest element.
Zana campiosi. I 1010 of disprove that IV, & oden have a feast and a greatest element.

Gcd definition

Gcd examples

Why do we restrict to the situation where a and b are not both zero?

Calculate gcd((10, 15))

Calculate gcd((10, 20))

Gcd basic claims

Claim:	For	any	integers	a, b	(not	both	zero)	, qcd((a,b)) > 1.
--------	-----	-----	----------	------	------	------	-------	--------	-------	--------

Proof: Show that 1 is a common factor of any two integers, so since the gcd is the greatest common factor it is greater than or equal to any common factor.

Claim: For any positive integers a,b, gcd((a,b) $) \leq a$ and gcd((a,b) $) \leq b$.

Proof Using the definition of gcd and the fact that factors of a positive integer are less than or equal to that integer.

Claim: For any positive integers a, b, if a divides b then gcd((a, b)) = a.

Proof Using previous claim and definition of gcd.

Claim: For any positive integers a, b, c, if there is some integer q such that a = bq + c,

$$\gcd(\ (a,b)\)=\gcd(\ (b,c)\)$$

Proof Prove that a	ny common divisor o	of a, b divides c and th	nat any common divisor	r of b, c divides a .

Gcd lemma relatively prime

Lemma: For any integers p,q (not both zero), $\gcd\left(\left(\frac{p}{\gcd((p,q))},\frac{q}{\gcd((p,q))}\right)\right)=1$. In other words, can reduce to relatively prime integers by dividing by \gcd .

Proof:

Let x be arbitrary positive integer and assume that x is a factor of each of $\frac{p}{\gcd((p,q))}$ and $\frac{q}{\gcd((p,q))}$. This gives integers α , β such that

$$\alpha x = \frac{p}{\gcd((p,q))}$$
 $\beta x = \frac{q}{\gcd((p,q))}$

Multiplying both sides by the denominator in the RHS:

$$\alpha x \cdot gcd((p,q)) = p$$
 $\beta x \cdot gcd((p,q)) = q$

In other words, $x \cdot gcd(p,q)$ is a common divisor of p,q. By definition of gcd, this means

$$x \cdot gcd((p,q)) \le gcd((p,q))$$

and since $\gcd(\ (p,q)\)$ is positive, this means, $x\leq 1.$

Sets numbers subsets

We have the following subset relationships between sets of numbers:

$$\mathbb{Z}^+ \subsetneq \mathbb{N} \subsetneq \mathbb{Z} \subsetneq \mathbb{Q} \subsetneq \mathbb{R}$$

Which of the proper subset inclusions above can you prove?

Definitions set prereqs

Term	Notation Example(s)	We say in English
all reals	\mathbb{R}	The (set of all) real numbers (numbers on the number
		line)
all integers	\mathbb{Z}	The (set of all) integers (whole numbers including neg-
		atives, zero, and positives)
all positive integers	\mathbb{Z}^+	The (set of all) strictly positive integers
all natural numbers	N	The (set of all) natural numbers. Note : we use the
		convention that 0 is a natural number.

Defining sets

To define sets:

To define a set using **roster method**, explicitly list its elements. That is, start with { then list elements of the set separated by commas and close with }.

To define a set using **set builder definition**, either form "The set of all x from the universe U such that x is ..." by writing

$$\{x \in U \mid ...x...\}$$

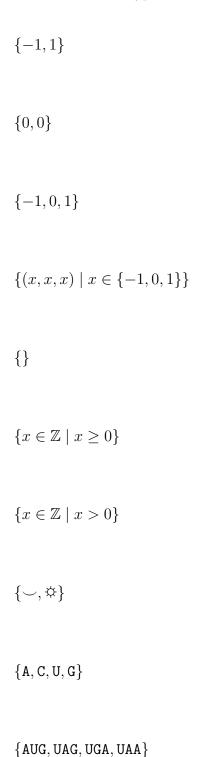

or form "the collection of all outputs of some operation when the input ranges over the universe U" by writing

$$\{...x... \mid x \in U\}$$

We use the symbol \in as "is an element of" to indicate membership in a set.

Example sets: For each of the following, identify whether it's defined using the roster method or set builder notation and give an example element.

Set operations

To define a set we can use the roster method, set builder notation, a recursive definition, and also we can apply a set operation to other sets.

New! Cartesian product of sets and set-wise concatenation of sets of strings

Definition: Let X and Y be sets. The **Cartesian product** of X and Y, denoted $X \times Y$, is the set of all ordered pairs (x, y) where $x \in X$ and $y \in Y$

$$X \times Y = \{(x, y) \mid x \in X \text{ and } y \in Y\}$$

Conventions: (1) Cartesian products can be chained together to result in sets of n-tuples and (2) When we form the Cartesian product of a set with itself $X \times X$ we can denote that set as X^2 , or X^n for the Cartesian product of a set with itself n times for a positive integer n.

Definition: Let X and Y be sets of strings over the same alphabet. The **set-wise concatenation** of X and Y, denoted $X \circ Y$, is the set of all results of string concatenation xy where $x \in X$ and $y \in Y$

$$X \circ Y = \{xy \mid x \in X \text{ and } y \in Y\}$$

Pro-tip: the meaning of writing one element next to another like xy depends on the data-types of x and y. When x and y are strings, the convention is that xy is the result of string concatenation. When x and y are numbers, the convention is that xy is the result of multiplication. This is (one of the many reasons) why is it very important to declare the data-type of variables before we use them.

Fill in the missing entries in the table:

Set	Example elements in this set and their data type:
B	A C G U
	(A,C) (U,U)
$B \times \{-1, 0, 1\}$	
$\{-1,0,1\} \times B$	
	(0, 0, 0)
$\{\mathtt{A},\mathtt{C},\mathtt{G},\mathtt{U}\}\circ\{\mathtt{A},\mathtt{C},\mathtt{G},\mathtt{U}\}$	
	GGGG

Definitions functions prereqs

Term	Notation Example(s)	We say in English		
sequence	x_1, \ldots, x_n	A sequence x_1 to x_n		
summation	$\sum_{i=1}^{n} x_i \text{ or } \sum_{i=1}^{n} x_i$	The sum of the terms of the sequence x_1 to x_n		
piecewise rule definition	$f(x) = \begin{cases} \text{rule 1 for } x & \text{when COND 1} \\ \text{rule 2 for } x & \text{when COND 2} \end{cases}$	Define f of x to be the result of applying rule 1 to x when condition COND 1 is true and the result of applying rule 2 to x when condition COND 2 is true. This can be generalized to having more than two conditions (or cases).		
function applica-	f(7)	f of 7 or f applied to 7 or the image of 7 under f		
UOII	f(z)	f of z or f applied to z or the image of z under f		
	f(g(z))	f of g of z or f applied to the result of g applied to z		
absolute value	-3	The absolute value of -3		
square root	$\sqrt{9}$	The non-negative square root of 9		

Pro-tip: the meaning of two vertical lines | | depends on the data-types of what's between the lines. For example, when placed around a number, the two vertical lines represent absolute value. We've seen a single vertial line | used as part of set builder definitions to represent "such that". Again, this is (one of the many reasons) why is it very important to declare the data-type of variables before we use them.
