## Algorithm redundancy

Real-life representations are often prone to corruption. Biological codes, like RNA, may mutate naturally<sup>1</sup> and during measurement; cosmic radiation and other ambient noise can flip bits in computer storage<sup>2</sup>. One way to recover from corrupted data is to introduce or exploit redundancy.

Consider the following algorithm to introduce redundancy in a string of 0s and 1s.

#### Create redundancy by repeating each bit three times

```
procedure redun3(a_{k-1}\cdots a_0): a nonempty bitstring)

for i:=0 to k-1

c_{3i}:=a_i

c_{3i+1}:=a_i

c_{3i+2}:=a_i

return c_{3k-1}\cdots c_0
```

#### Decode sequence of bits using majority rule on consecutive three bit sequences

```
procedure decode3(c_{3k-1}\cdots c_0): a nonempty bitstring whose length is an integer multiple of 3)

for i:=0 to k-1

if exactly two or three of c_{3i}, c_{3i+1}, c_{3i+2} are set to 1

a_i:=1

else

a_i:=0

return a_{k-1}\cdots a_0
```

Give a recursive definition of the set of outputs of the redun3 procedure, Out,

Consider the message m = 0001 so that the sender calculates redun3(m) = redun3(0001) = 000000000111.

Introduce \_\_\_\_ errors into the message so that the signal received by the receiver is \_\_\_\_\_ but the receiver is still able to decode the original message.

Challenge: what is the biggest number of errors you can introduce?

Building a circuit for lines 3-6 in *decode* procedure: given three input bits, we need to determine whether the majority is a 0 or a 1.

$c_{3i}$	$c_{3i+1}$	$c_{3i+2}$	$a_i$
1	1	1	
1	1	0	
1	0	1	
1	0	0	
0	1	1	
0	1	0	
0	0	1	
0	0	0	

Circuit

<sup>&</sup>lt;sup>1</sup>Mutations of specific RNA codons have been linked to many disorders and cancers.

<sup>&</sup>lt;sup>2</sup>This RadioLab podcast episode goes into more detail on bit flips: https://www.wnycstudios.org/story/bit-flip

### Cartesian product definition

**Definition**: The **Cartesian product** of the sets A and B,  $A \times B$ , is the set of all ordered pairs (a, b), where  $a \in A$  and  $b \in B$ . That is:  $A \times B = \{(a, b) \mid (a \in A) \land (b \in B)\}$ . The Cartesian product of the sets  $A_1, A_2, \ldots, A_n$ , denoted by  $A_1 \times A_2 \times \cdots \times A_n$ , is the set of ordered n-tuples  $(a_1, a_2, \ldots, a_n)$ , where  $a_i$  belongs to  $A_i$  for  $i = 1, 2, \ldots, n$ . That is,

$$A_1 \times A_2 \times \cdots \times A_n = \{(a_1, a_2, \dots, a_n) \mid a_i \in A_i \text{ for } i = 1, 2, \dots, n\}$$

## Rna mutation insertion deletion example

Trace the pseudocode to find the output of mutation (AUC, 3, G))

Fill in the blanks so that  $insertion(\ (AUC, \_, \_)\ ) = AUCG$ 

Fill in the blanks so that  $deletion(\ (\_,\_)\ ) = {\tt G}$ 

#### Rna rnalen basecount definitions

Recall the definitions: The set of RNA strands S is defined (recursively) by:

Basis Step:  $A \in S, C \in S, U \in S, G \in S$ 

Recursive Step: If  $s \in S$  and  $b \in B$ , then  $sb \in S$ 

where sb is string concatenation.

The function rnalen that computes the length of RNA strands in S is defined recursively by:

Basis Step: If  $b \in B$  then  $rnalen: S \to \mathbb{Z}^+$ rnalen(b) = 1

Recursive Step: If  $s \in S$  and  $b \in B$ , then rnalen(sb) = 1 + rnalen(s)

The function basecount that computes the number of a given base b appearing in a RNA strand s is defined recursively by:

$$\begin{array}{lll} basecount: S \times B & \rightarrow \mathbb{N} \\ \text{Basis Step:} & \text{If } b_1 \in B, b_2 \in B & basecount(\ (b_1, b_2)\ ) & = \begin{cases} 1 & \text{when } b_1 = b_2 \\ 0 & \text{when } b_1 \neq b_2 \end{cases} \\ \text{Recursive Step:} & \text{If } s \in S, b_1 \in B, b_2 \in B & basecount(\ (sb_1, b_2)\ ) & = \begin{cases} 1 + basecount(\ (s, b_2)\ ) & \text{when } b_1 = b_2 \\ basecount(\ (s, b_2)\ ) & \text{when } b_1 \neq b_2 \end{cases}$$

## Proof strategies quantification finite domain

When a predicate P(x) is over a **finite** domain:

- To show that  $\forall x P(x)$  is true: check that P(x) evaluates to T at each domain element by evaluating over and over. This is called "Proof of universal by **exhaustion**".
- To show that  $\forall x P(x)$  is false: find a **counterexample**, a domain element where P(x) evaluates to F.
- To show that  $\exists x P(x)$  is true: find a witness, a domain element where P(x) evaluates to T.
- To show that  $\exists x P(x)$  is false: check that P(x) evaluates to F at each domain element by evaluating over and over. DeMorgan's Law gives that  $\neg \exists x P(x) \equiv \forall x \neg P(x)$  so this amounts to a proof of universal by exhaustion.

### Proof strategy universal generalization

**New!** Proof by universal generalization: To prove that  $\forall x P(x)$  is true, we can take an arbitrary element e from the domain of quantification and show that P(e) is true, without making any assumptions about e other than that it comes from the domain.

An **arbitrary** element of a set or domain is a fixed but unknown element from that set.

### Quiz translating counting quantifiers

Suppose P(x) is a predicate over a domain D.

1. True or False: To translate the statement "There are at least two elements in D where the predicate P evaluates to true", we could write

$$\exists x_1 \in D \,\exists x_2 \in D \, (P(x_1) \land P(x_2))$$

2. True or False: To translate the statement "There are at most two elements in D where the predicate P evaluates to true", we could write

$$\forall x_1 \in D \ \forall x_2 \in D \ \forall x_3 \in D \ (\ (P(x_1) \land P(x_2) \land P(x_3)\ ) \rightarrow (\ x_1 = x_2 \lor x_2 = x_3 \lor x_1 = x_3\ )\ )$$

### Sets equality subset definition

#### **Definitions:**

A set is an unordered collection of elements. When A and B are sets, A = B (set equality) means

$$\forall x (x \in A \leftrightarrow x \in B)$$

When A and B are sets,  $A \subseteq B$  ("A is a subset of B") means

$$\forall x (x \in A \to x \in B)$$

When A and B are sets,  $A \subseteq B$  ("A is a **proper subset** of B") means

$$(A \subseteq B) \land (A \neq B)$$

### Proof strategies conditionals

**New! Proof of conditional by direct proof**: To prove that the conditional statement  $p \to q$  is true, we can assume p is true and use that assumption to show q is true.

New! Proof of conditional by contrapositive proof: To prove that the implication  $p \to q$  is true, we can assume q is false and use that assumption to show p is also false.

**New! Proof of disjuction using equivalent conditional**: To prove that the disjunction  $p \lor q$  is true, we can rewrite it equivalently as  $\neg p \to q$  and then use direct proof or contrapositive proof.

### Proof strategies proof by cases

**New! Proof by Cases**: To prove q, we can work by cases by first describing all possible cases we might be in and then showing that each one guarantees q. Formally, if we know that  $p_1 \vee p_2$  is true, and we can show that  $(p_1 \to q)$  is true and we can show that  $(p_2 \to q)$ , then we can conclude q is true.

### Proof strategies ands

New! Proof of conjunctions with subgoals: To show that  $p \wedge q$  is true, we have two subgoals: subgoal (1) prove p is true; and, subgoal (2) prove q is true.

To show that  $p \wedge q$  is false, it's enough to prove that  $\neg p$ . To show that  $p \wedge q$  is false, it's enough to prove that  $\neg q$ .

#### Sets proof strategies

To prove that one set is a subset of another, e.g. to show  $A \subseteq B$ :

To prove that two sets are equal, e.g. to show A = B:

# Sets equality example

Example:  $\{43, 7, 9\} = \{7, 43, 9, 7\}$ 

# Sets basic proofs

**Prove** or **disprove**: 
$$\{4,6\} \subseteq \{n \mid \exists c \in \mathbb{Z}(n=4c)\}$$

**Prove** or **disprove**: 
$$\{4,6\} \subseteq \{n \text{ mod } 10 \mid \exists c \in \mathbb{Z}(n=4c)\}$$

# Proofs signposting

Consider, an <b>arbitrary Assume</b> , we <b>wan</b> the proof is complete $\square$ .	t to show that	Which is what	was needed, so
or, in other words:			
Let be an $\mathbf{arbitrary}$ $\mathbf{Assume}$ , $\mathbf{WTS}$ that	QED.		

# Set operations union intersection powerset

Cartesian product: When A and B are sets,

$$A \times B = \{(a, b) \mid a \in A \land b \in B\}$$

Example:  $\{43, 9\} \times \{9, \mathbb{Z}\} =$ 

Example:  $\mathbb{Z} \times \emptyset =$ 

**Union**: When A and B are sets,

$$A \cup B = \{x \mid x \in A \lor x \in B\}$$

Example:  $\{43, 9\} \cup \{9, \mathbb{Z}\} =$ 

Example:  $\mathbb{Z} \cup \emptyset =$ 

**Intersection**: When A and B are sets,

$$A \cap B = \{x \mid x \in A \land x \in B\}$$

Example:  $\{43, 9\} \cap \{9, \mathbb{Z}\} =$ 

Example:  $\mathbb{Z} \cap \emptyset =$ 

**Set difference**: When A and B are sets,

$$A - B = \{x \mid x \in A \land x \notin B\}$$

Example:  $\{43, 9\} - \{9, \mathbb{Z}\} =$ 

Example:  $\mathbb{Z} - \emptyset =$ 

**Disjoint sets**: sets A and B are disjoint means  $A \cap B = \emptyset$ 

Example:  $\{43,9\},\{9,\mathbb{Z}\}$  are not disjoint

Example: The sets  $\mathbb Z$  and  $\emptyset$  are disjoint

Power set: When U is a set,  $\mathcal{P}(U) = \{X \mid X \subseteq U\}$ 

Example:  $\mathcal{P}(\{43,9\}) =$ 

Example:  $\mathcal{P}(\emptyset) =$ 

# Logical operators full truth table

Input	Output					
	Conjunction	Exclusive or	Disjunction	Conditional	Biconditional	
p q	$p \wedge q$	$p\oplus q$	$p \lor q$	$p \to q$	$p \leftrightarrow q$	
T $T$	T	F	T	T	T	
T F	F	T	T	F	F

# Hypothesis conclusion

The only way to make the conditional statement $p \to q$ false is to					
The <b>hypothesis</b> of $p \to q$ is	The <b>antecedent</b> of $p \to q$ is				
The <b>conclusion</b> of $p \to q$ is	The <b>consequent</b> of $p \to q$ is				

# Converse inverse contrapositive

The <b>converse</b> of $p \to q$ is	
The <b>inverse</b> of $p \to q$ is	
The <b>contrapositive</b> of $p \to q$ is	

### Compound propositions recursive definition

We can use a recursive definition to describe all compound propositions that use propositional variables from a specified collection. Here's the definition for all compound propositions whose propositional variables are in  $\{p,q\}$ .

Basis Step: p and q are each a compound proposition

Recursive Step: If x is a compound proposition then so is  $(\neg x)$  and if

x and y are both compound propositions then so is each of

 $(x \land y), (x \oplus y), (x \lor y), (x \to y), (x \leftrightarrow y)$ 

# Compound propositions precedence

Order of operations (Precedence) for logical operators:

Negation, then conjunction / disjunction, then conditional / biconditionals.

Example:  $\neg p \lor \neg q \text{ means } (\neg p) \lor (\neg q).$ 

# Logical equivalence identities

#### (Some) logical equivalences

Can replace p and q with any compound proposition

$$\neg(\neg p) \equiv p$$

Double negation

$$p \lor q \equiv q \lor p \qquad \qquad p \land q \equiv q \land p$$

$$p \wedge q \equiv q \wedge p$$

Commutativity Ordering of terms

$$(p \lor q) \lor r \equiv p \lor (q \lor r)$$

$$(p \wedge q) \wedge r \equiv p \wedge (q \wedge r)$$

 $(p \lor q) \lor r \equiv p \lor (q \lor r)$   $(p \land q) \land r \equiv p \land (q \land r)$  Associativity Grouping of terms

$$p \wedge F \equiv F$$

$$p \lor T \equiv T \quad p \land T \equiv p$$

$$p \vee F \equiv$$

 $p \wedge F \equiv F$   $p \vee T \equiv T$   $p \wedge T \equiv p$   $p \vee F \equiv p$  **Domination** aka short circuit evaluation

$$\neg (p \land q) \equiv \neg p \lor \neg q$$

$$\neg(p \lor q) \equiv \neg p \land \neg q$$

 $\neg(p \land q) \equiv \neg p \lor \neg q$   $\neg(p \lor q) \equiv \neg p \land \neg q$  DeMorgan's Laws

$$p \to q \equiv \neg p \lor q$$

$$p \to q \equiv \neg q \to \neg p \qquad \text{ Contrapositive }$$

$$\neg(p \to q) \equiv p \land \neg q$$

$$\neg(p \leftrightarrow q) \equiv p \oplus q$$

$$p \leftrightarrow q \equiv q \leftrightarrow p$$

Extra examples:

 $p \leftrightarrow q$  is not logically equivalent to  $p \land q$  because

 $p \to q$  is not logically equivalent to  $q \to p$  because

## Logical operators english synonyms

#### Common ways to express logical operators in English:

**Negation**  $\neg p$  can be said in English as

- Not p.
- It's not the case that p.
- p is false.

Conjunction  $p \wedge q$  can be said in English as

- p and q.
- Both p and q are true.
- p but q.

**Exclusive or**  $p \oplus q$  can be said in English as

- p or q, but not both.
- Exactly one of p and q is true.

**Disjunction**  $p \lor q$  can be said in English as

- p or q, or both.
- p or q (inclusive).
- At least one of p and q is true.

Conditional  $p \to q$  can be said in English as

- if p, then q.
- p is sufficient for q.
- q when p.
- q whenever p.
- p implies q.
- Biconditional
  - p if and only if q.
  - p iff q.
  - $\bullet$  If p then q, and conversely.
  - ullet p is necessary and sufficient for q.

- q follows from p.
- p is sufficient for q.
- q is necessary for p.
- p only if q.

### Compound propositions translation

**Translation**: Express each of the following sentences as compound propositions, using the given propositions.

"A sufficient condition for the warranty to be good is w is "the warranty is good" that you bought the computer less than a year ago" b is "you bought the computer less than a year ago"

"Whenever the message was sent from an unknown s is "The message is scanned for viruses" system, it is scanned for viruses." u is "The message was sent from an unknown system"

"I will complete my to-do list only if I put a reminder in my calendar"

d is "I will complete my to-do list"c is "I put a reminder in my calendar"

### Consistency def

**Definition**: A collection of compound propositions is called **consistent** if there is an assignment of truth values to the propositional variables that makes each of the compound propositions true.

#### Predicate definition

**Definition**: A **predicate** is a function from a given set (domain) to  $\{T, F\}$ .

A predicate can be applied, or **evaluated** at, an element of the domain.

Usually, a predicate describes a property that domain elements may or may not have.

Two predicates over the same domain are **equivalent** means they evaluate to the same truth values for all possible assignments of domain elements to the input. In other words, they are equivalent means that they are equal as functions.

To define a predicate, we must specify its domain and its value at each domain element. The rule assigning truth values to domain elements can be specified using a formula, English description, in a table (if the domain is finite), or recursively (if the domain is recursively defined).

# Predicate examples finite domain

Input	Output			
	V(x)	N(x)	Mystery(x)	
x	$V(x)$ $[x]_{2c,3} > 0$	$[x]_{2c,3} < 0$		
000	F		$\overline{T}$	
001	T		T	
010	T		T	
011	T		F	
100	F		F	
101	F		T	
110	F		F	
111	F		T	

The domain for each of the predicates $V(x)$ , $N(x)$ , $Mystery(x)$ is	,
---	---

Fill in the table of values for the predicate N(x) based on the formula given.

#### Predicate truth set definition

**Definition**: The **truth set** of a predicate is the collection of all elements in its domain where the predicate evaluates to T.

Notice that specifying the domain and the truth set is sufficient for defining a predicate.

# Predicate truth set example

The truth set for the predicate $V(x)$ is	·	
The truth set for the predicate $N(x)$ is	·	
The truth set for the predicate $Mystery(x)$ is		

# Quantification definition

The universal quantification of predicate P(x) over domain U is the statement "P(x) for all values of x in the domain U" and is written  $\forall x P(x)$  or  $\forall x \in U P(x)$ . When the domain is finite, universal quantification over the domain is equivalent to iterated *conjunction* (ands).

The existential quantification of predicate P(x) over domain U is the statement "There exists an element x in the domain U such that P(x)" and is written  $\exists x P(x)$  for  $\exists x \in U \ P(x)$ . When the domain is finite, existential quantification over the domain is equivalent to iterated disjunction (ors).

An element for which P(x) = F is called a **counterexample** of  $\forall x P(x)$ .

An element for which P(x) = T is called a witness of  $\exists x P(x)$ .

## Quantification logical equivalence

Statements involving predicates and quantifiers are logically equivalent means they have the same truth value no matter which predicates (domains and functions) are substituted in.

Quantifier version of De Morgan's laws:  $|\neg \forall x P(x) \equiv \exists x (\neg P(x))|$ 

# Quantification examples finite domain

Examples of quantifications using V(x), N(x), Mystery(x):

True or False:  $\exists x \ (V(x) \land N(x))$ 

True or False:  $\forall x \ (V(x) \to N(x))$ 

**True** or **False**:  $\exists x \ (\ N(x) \leftrightarrow Mystery(x)\ )$ 

Rewrite  $\neg \forall x \ (V(x) \oplus Mystery(x))$  into a logical equivalent statement.

Notice that these are examples where the predicates have *finite* domain. How would we evaluate quantifications where the domain may be infinite?

#### Rna rnalen basecount definitions

Recall the definitions: The set of RNA strands S is defined (recursively) by:

Basis Step:  $A \in S, C \in S, U \in S, G \in S$ 

Recursive Step: If  $s \in S$  and  $b \in B$ , then  $sb \in S$ 

where sb is string concatenation.

The function rnalen that computes the length of RNA strands in S is defined recursively by:

 $rnalen: S \rightarrow \mathbb{Z}^+$ 

Basis Step: If  $b \in B$  then rnalen(b) = 1

Recursive Step: If  $s \in S$  and  $b \in B$ , then rnalen(sb) = 1 + rnalen(s)

The function basecount that computes the number of a given base b appearing in a RNA strand s is defined recursively by:

## Predicate rna example

Example predicates on S, the set of RNA strands (an infinite set)

 $H: S \to \{T, F\}$  where H(s) = T for all s.

Truth set of H is

 $F_{\mathtt{A}}:S \to \{T,F\}$  defined recursively by:

Basis step:  $F_{\mathbf{A}}(\mathbf{A}) = T$ ,  $F_{\mathbf{A}}(\mathbf{C}) = F_{\mathbf{A}}(\mathbf{G}) = F_{\mathbf{A}}(\mathbf{U}) = F$ 

Recursive step: If  $s \in S$  and  $b \in B$ , then  $F_{A}(sb) = F_{A}(s)$ .

Example where  $F_{A}$  evaluates to T is \_\_\_\_\_

Example where  $F_{A}$  evaluates to F is \_\_\_\_\_

# Predicates example rnalen basecount

Using functions to define predicates:

L with domain  $S \times \mathbb{Z}^+$  is defined by, for  $s \in S$  and  $n \in \mathbb{Z}^+$ ,

$$L((s,n)) = \begin{cases} T & \text{if } rnalen(s) = n \\ F & \text{otherwise} \end{cases}$$

In other words, L((s,n)) means rnalen(s) = n

BC with domain  $S \times B \times \mathbb{N}$  is defined by, for  $s \in S$  and  $b \in B$  and  $n \in \mathbb{N}$ ,

$$BC((s,b,n)) = \begin{cases} T & \text{if } basecount((s,b)) = n \\ F & \text{otherwise} \end{cases}$$

In other words,  $BC(\ (s,b,n)\ )$  means  $basecount(\ (s,b)\ )=n$ 

Example where L evaluates to T: \_\_\_\_\_ Why?

Example where BC evaluates to T: Why?

Example where L evaluates to F: \_\_\_\_\_ Why?

Example where BC evaluates to F: Why?

$$\exists t \ BC(t) \qquad \exists (s,b,n) \in S \times B \times \mathbb{N} \ (basecount(\ (s,b)\ ) = n)$$

In English:

Witness that proves this existential quantification is true:

$$\forall t \ BC(t) \qquad \qquad \forall (s,b,n) \in S \times B \times \mathbb{N} \ (basecount(\ (s,b)\ ) = n)$$

In English:

Counterexample that proves this universal quantification is false:

# Predicates projecting example rna basecount

#### New predicates from old

1. Define the **new** predicate with domain  $S \times B$  and rule

$$basecount((s,b)) = 3$$

Example domain element where predicate is T:

2. Define the **new** predicate with domain  $S \times \mathbb{N}$  and rule

$$basecount(\ (s,\mathtt{A})\ )=n$$

Example domain element where predicate is T:

3. Define the **new** predicate with domain  $S \times B$  and rule

$$\exists n \in \mathbb{N} \ (basecount(\ (s,b)\ ) = n)$$

Example domain element where predicate is T:

4. Define the **new** predicate with domain S and rule

$$\forall b \in B \ (basecount(\ (s,b)\ )=1)$$

Example domain element where predicate is T:

#### Predicate notation

**Notation**: for a predicate P with domain  $X_1 \times \cdots \times X_n$  and a n-tuple  $(x_1, \ldots, x_n)$  with each  $x_i \in X$ , we can write  $P(x_1, \ldots, x_n)$  to mean  $P((x_1, \ldots, x_n))$ .

# Nested quantifiers

#### Nested quantifiers

$$\forall s \in S \ \forall b \in B \ \forall n \in \mathbb{N} \ (basecount(\ (s,b)\ ) = n)$$

In English:

Counterexample that proves this universal quantification is false:

$$\forall n \in \mathbb{N} \ \forall s \in S \ \forall b \in B \ (basecount(\ (s,b)\ ) = n)$$

In English:

Counterexample that proves this universal quantification is false:

# Compound proposition definitions

**Proposition**: Declarative sentence that is true or false (not both).

**Propositional variable**: Variable that represents a proposition.

**Compound proposition**: New proposition formed from existing propositions (potentially) using logical operators. *Note*: A propositional variable is one example of a compound proposition.

**Truth table**: Table with one row for each of the possible combinations of truth values of the input and an additional column that shows the truth value of the result of the operation corresponding to a particular row.

### Logical equivalence

Logical equivalence: Two compound propositions are logically equivalent means that they have the same truth values for all settings of truth values to their propositional variables.

**Tautology**: A compound proposition that evaluates to true for all settings of truth values to its propositional variables; it is abbreviated T.

Contradiction: A compound proposition that evaluates to false for all settings of truth values to its propositional variables; it is abbreviated F.

**Contingency**: A compound proposition that is neither a tautology nor a contradiction.

# Tautology contradiction contingency examples

 $p \wedge p$ 

 $p \oplus p$ 

 $p \lor p$ 

 $p \vee \neg p$ 

 $p \land \neg p$ 

## Logical equivalence extra example

Extra Example: Which of the compound propositions in the table below are logically equivalent?

Inp	out	Output				
p	q	$\neg (p \land \neg q)$	$\neg (\neg p \lor \neg q)$	$(\neg p \lor q)$	$(\neg q \lor \neg p)$	$(p \land q)$
$\overline{T}$	T					
T	F					
F	T					
F	F					

## Algorithm definition

New! An algorithm is a finite sequence of precise instructions for solving a problem.

Algorithms can be expressed in English or in more formalized descriptions like pseudocode or fully executable programs.

Sometimes, we can define algorithms whose output matches the rule for a function we already care about. Consider the (integer) logarithm function

$$logb: \{b \in \mathbb{Z} \mid b > 1\} \times \mathbb{Z}^+ \rightarrow \mathbb{N}$$

defined by

 $logb((b,n)) = greatest integer y so that b^y is less than or equal to n$ 

#### Calculating integer part of base b logarithm

```
procedure logb(b,n): positive integers with b>1)

i:=0

while n>b-1

i:=i+1

n:=n div b

return i {i holds the integer part of the base b logarithm of n}
```

Trace this algorithm with inputs b = 3 and n = 17

	b	n	i	n > b - 1?
Initial value	3	17		
After 1 iteration				
After 2 iterations				
After 3 iterations				

Compare: does the output match the rule for the (integer) logarithm function?

### Fixed width definition

**Definition** For b an integer greater than 1, w a positive integer, and n a nonnegative integer \_\_\_\_\_, the base b fixed-width w expansion of n is

$$(a_{w-1}\cdots a_1a_0)_{b,w}$$

where  $a_0, a_1, \ldots, a_{w-1}$  are nonnegative integers less than b and

$$n = \sum_{i=0}^{w-1} a_i b^i$$

# Fixed width example

Decimal	Binary	Binary fixed-width 10	Binary fixed-width 7	Binary fixed-width 4
b = 10	b=2	b = 2, w = 10	b = 2, w = 7	b = 2, w = 4
$(20)_{10}$				

#### Fixed width fractional definition

**Definition** For b an integer greater than 1, w a positive integer, w' a positive integer, and x a real number the base b fixed-width expansion of x with integer part width w and fractional part width w' is  $(a_{w-1} \cdots a_1 a_0.c_1 \cdots c_{w'})_{b,w,w'}$  where  $a_0, a_1, \ldots, a_{w-1}, c_1, \ldots, c_{w'}$  are nonnegative integers less than b and

$$x \ge \sum_{i=0}^{w-1} a_i b^i + \sum_{j=1}^{w'} c_j b^{-j}$$
 and  $x < \sum_{i=0}^{w-1} a_i b^i + \sum_{j=1}^{w'} c_j b^{-j} + b^{-w'}$ 

Note: Java uses floating point, not fixed width representation, but similar rounding errors appear in both.

# Negative int expansions

Representing negative integers in binary: Fix a positive integer width for the representation w, w > 1.

	To represent a positive integer $n$	To represent a negative integer $-n$
Sign-magnitude	$[0a_{w-2}\cdots a_0]_{s,w}$ , where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $n=17, w=7$ :	$[1a_{w-2}\cdots a_0]_{s,w}$ , where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $-n=-17, w=7$ :
2s complement	$[0a_{w-2}\cdots a_0]_{2c,w}$ , where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $n=17, w=7$ :	$[1a_{w-2}\cdots a_0]_{2c,w}$ , where $2^{w-1}-n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $-n=-17,\ w=7$ :

# Calculating 2s complement

For positive integer n, to represent -n in 2s complement with width w,

- Calculate  $2^{w-1} n$ , convert result to binary fixed-width w 1, pad with leading 1, or
- Express -n as a sum of powers of 2, where the leftmost  $2^{w-1}$  is negative weight, or
- Convert n to binary fixed-width w, flip bits, add 1 (ignore overflow)

Challenge: use definitions to explain why each of these approaches works.

### Representing zero

#### Representing 0:

So far, we have representations for positive and negative integers. What about 0?

	To represent a <b>non-negative</b> integer $n$	To represent a <b>non-positive</b> integer $-n$
Sign-magnitude	$[0a_{w-2}\cdots a_0]_{s,w}$ , where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $n=0,w=7$ :	$[1a_{w-2}\cdots a_0]_{s,w}$ , where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $-n=0, w=7$ :
2s complement	$[0a_{w-2}\cdots a_0]_{2c,w}$ , where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $n=0, \ w=7$ :	$[1a_{w-2}\cdots a_0]_{2c,w}$ , where $2^{w-1}-n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $-n=0, w=7$ :

#### Netflix intro

What data should we encode about each Netflix account holder to help us make effective recommendations?

In machine learning, clustering can be used to group similar data for prediction and recommendation. For example, each Netflix user's viewing history can be represented as a n-tuple indicating their preferences about movies in the database, where n is the number of movies in the database. People with similar tastes in movies can then be clustered to provide recommendations of movies for one another. Mathematically, clustering is based on a notion of distance between pairs of n-tuples.

# Data types

Term	Examples:	
	(add additional	examples from class)
set	$7 \in \{43, 7, 9\}$	$2 \notin \{43, 7, 9\}$
unordered collection of elements		
repetition doesn't matter		
Equal sets agree on membership of all elements		
n-tuple		
ordered sequence of elements with $n$ "slots" $(n > 0)$		
repetition matters, fixed length		
Equal n-tuples have corresponding components equal		

#### string

ordered finite sequence of elements each from specified set (called the alphabet over which the string is defined) repetition matters, arbitrary finite length Equal strings have same length and corresponding characters equal

#### Special cases:

When n = 2, the 2-tuple is called an **ordered pair**.

A string of length 0 is called the **empty string** and is denoted  $\lambda$ .

A set with no elements is called the **empty set** and is denoted  $\{\}$  or  $\emptyset$ .

#### Set operations

To define a set we can use the roster method, set builder notation, a recursive definition, and also we can apply a set operation to other sets.

New! Cartesian product of sets and set-wise concatenation of sets of strings

**Definition**: Let X and Y be sets. The **Cartesian product** of X and Y, denoted  $X \times Y$ , is the set of all ordered pairs (x, y) where  $x \in X$  and  $y \in Y$ 

$$X \times Y = \{(x, y) \mid x \in X \text{ and } y \in Y\}$$

Conventions: (1) Cartesian products can be chained together to result in sets of n-tuples and (2) When we form the Cartesian product of a set with itself  $X \times X$  we can denote that set as  $X^2$ , or  $X^n$  for the Cartesian product of a set with itself n times for a positive integer n.

**Definition**: Let X and Y be sets of strings over the same alphabet. The **set-wise concatenation** of X and Y, denoted  $X \circ Y$ , is the set of all results of string concatenation xy where  $x \in X$  and  $y \in Y$ 

$$X \circ Y = \{xy \mid x \in X \text{ and } y \in Y\}$$

**Pro-tip**: the meaning of writing one element next to another like xy depends on the data-types of x and y. When x and y are strings, the convention is that xy is the result of string concatenation. When x and y are numbers, the convention is that xy is the result of multiplication. This is (one of the many reasons) why is it very important to declare the data-type of variables before we use them.

Fill in the missing entries in the table:

Set	Example elements in this set and their data type:
B	A C G U
	(A,C) $(U,U)$
$B \times \{-1, 0, 1\}$	
$\{-1,0,1\} \times B$	
	(0, 0, 0)
$\{\mathtt{A},\mathtt{C},\mathtt{G},\mathtt{U}\}\circ\{\mathtt{A},\mathtt{C},\mathtt{G},\mathtt{U}\}$	
	GGGG

# Defining functions

**New! Defining functions** A function is defined by its (1) domain, (2) codomain, and (3) rule assigning each element in the domain exactly one element in the codomain.

The domain and codomain are nonempty sets.

The rule can be depicted as a table, formula, piecewise definition, or English description.

The notation is

"Let the function FUNCTION-NAME: DOMAIN  $\rightarrow$  CODOMAIN be given by FUNCTION-NAME(x) = ... for every  $x \in DOMAIN$ ".

or

"Consider the function FUNCTION-NAME: DOMAIN  $\rightarrow$  CODOMAIN defined as FUNCTION-NAME(x) = . . . for every  $x \in DOMAIN$ ".

Example: The absolute value function

Domain

Codomain

Rule

## Defining functions recursively

When the domain of a function is a recursively defined set, the rule assigning images to domain elements (outputs) can also be defined recursively.

Recall: The set of RNA strands S is defined (recursively) by:

Basis Step:  $A \in S, C \in S, U \in S, G \in S$ Recursive Step: If  $s \in S$  and  $b \in B$ , then  $sb \in S$ 

where sb is string concatenation.

**Definition** (Of a function, recursively) A function rnalen that computes the length of RNA strands in S is defined by:

The domain of rnalen is

The codomain of rnalen is

Example function application:

$$rnalen(ACU) =$$

Example: A function basecount that computes the number of a given base b appearing in a RNA strand s is defined recursively:
