	" p and q "	"p xor q"	" $p \text{ or } q$ "	"if p then q "	" p if and only if q "	

Hypothesis conclusion

The only way to make the conditional statement $p \to q$ false is to					
The hypothesis of $p \to q$ is	The antecedent of $p \to q$ is				
The conclusion of $p \to q$ is	The consequent of $p \to q$ is				

Converse inverse contrapositive

The converse of $p \to q$ is	
The inverse of $p \to q$ is	
The contrapositive of $p \to q$ is	

Compound propositions recursive definition

We can use a recursive definition to describe all compound propositions that use propositional variables from a specified collection. Here's the definition for all compound propositions whose propositional variables are in $\{p,q\}$.

Basis Step: p and q are each a compound proposition

Recursive Step: If x is a compound proposition then so is $(\neg x)$ and if

x and y are both compound propositions then so is each of

 $(x \land y), (x \oplus y), (x \lor y), (x \to y), (x \leftrightarrow y)$

Compound propositions precedence

Order of operations (Precedence) for logical operators:

Negation, then conjunction / disjunction, then conditional / biconditionals.

Example: $\neg p \lor \neg q \text{ means } (\neg p) \lor (\neg q).$

Logical equivalence identities

(Some) logical equivalences

Can replace p and q with any compound proposition

$$\neg(\neg p) \equiv p$$

Double negation

$$p \vee q \equiv q \vee p$$

$$p \lor q \equiv q \lor p \qquad \qquad p \land q \equiv q \land p$$

Commutativity Ordering of terms

$$(p \lor q) \lor r \equiv p \lor (q \lor r)$$

$$(p \wedge q) \wedge r \equiv p \wedge (q \wedge r)$$

 $(p \lor q) \lor r \equiv p \lor (q \lor r)$ $(p \land q) \land r \equiv p \land (q \land r)$ Associativity Grouping of terms

$$p \wedge F \equiv F$$

$$p \lor T \equiv T \quad p \land T \equiv p$$

$$p \vee F \equiv$$

 $p \wedge F \equiv F$ $p \vee T \equiv T$ $p \wedge T \equiv p$ $p \vee F \equiv p$ **Domination** aka short circuit evaluation

$$\neg (p \land q) \equiv \neg p \lor \neg q$$

$$\neg(p \lor q) \equiv \neg p \land \neg q$$

 $\neg(p \land q) \equiv \neg p \lor \neg q$ $\neg(p \lor q) \equiv \neg p \land \neg q$ DeMorgan's Laws

$$p \to q \equiv \neg p \lor q$$

$$p \to q \equiv \neg q \to \neg p$$
 Contrapositive

$$\neg(p \to q) \equiv p \land \neg q$$

$$\neg(p \leftrightarrow q) \equiv p \oplus q$$

$$p \leftrightarrow q \equiv q \leftrightarrow p$$

Extra examples:

 $p \leftrightarrow q$ is not logically equivalent to $p \land q$ because

 $p \to q$ is not logically equivalent to $q \to p$ because

Logical operators english synonyms

Common ways to express logical operators in English:

Negation $\neg p$ can be said in English as

- Not p.
- It's not the case that p.
- p is false.

Conjunction $p \wedge q$ can be said in English as

- p and q.
- Both p and q are true.
- p but q.

Exclusive or $p \oplus q$ can be said in English as

- p or q, but not both.
- Exactly one of p and q is true.

Disjunction $p \lor q$ can be said in English as

- p or q, or both.
- p or q (inclusive).
- At least one of p and q is true.

Conditional $p \to q$ can be said in English as

- if p, then q.
- p is sufficient for q.
- q when p.
- q whenever p.
- p implies q.
- Biconditional
 - p if and only if q.
 - p iff q.
 - ullet If p then q, and conversely.
 - ullet p is necessary and sufficient for q.

- q follows from p.
- p is sufficient for q.
- q is necessary for p.
- p only if q.

Compound propositions translation

Translation: Express each of the following sentences as compound propositions, using the given propositions.

"A sufficient condition for the warranty to be good is w is "the warranty is good" that you bought the computer less than a year ago" b is "you bought the computer less than a year ago"

"Whenever the message was sent from an unknown s is "The message is scanned for viruses" system, it is scanned for viruses." u is "The message was sent from an unknown system"

"I will complete my to-do list only if I put a reminder in my calendar"

d is "I will complete my to-do list"c is "I put a reminder in my calendar"

Consistency def

Definition: A collection of compound propositions is called **consistent** if there is an assignment of truth values to the propositional variables that makes each of the compound propositions true.

Predicate definition

Definition: A **predicate** is a function from a given set (domain) to $\{T, F\}$.

A predicate can be applied, or **evaluated** at, an element of the domain.

Usually, a predicate describes a property that domain elements may or may not have.

Two predicates over the same domain are **equivalent** means they evaluate to the same truth values for all possible assignments of domain elements to the input. In other words, they are equivalent means that they are equal as functions.

To define a predicate, we must specify its domain and its value at each domain element. The rule assigning truth values to domain elements can be specified using a formula, English description, in a table (if the domain is finite), or recursively (if the domain is recursively defined).

Predicate examples finite domain

Input		Output	
	V(x)	N(x)	Mystery(x)
x	$V(x)$ $[x]_{2c,3} > 0$	$[x]_{2c,3} < 0$	
000	F		\overline{T}
001	T		T
010	T		T
011	T		F
100	F		F
101	F		T
110	F		F
111	F		T

The domain for each of the predicates $V(x)$, $N(x)$, $Mystery(x)$ is	,
---	---

Fill in the table of values for the predicate N(x) based on the formula given.

Predicate truth set definition

Definition: The **truth set** of a predicate is the collection of all elements in its domain where the predicate evaluates to T.

Notice that specifying the domain and the truth set is sufficient for defining a predicate.

Predicate truth set example

The truth set for the predicate $V(x)$ is	·	
The truth set for the predicate $N(x)$ is		
The truth set for the predicate $Mystery(x)$ is		

Quantification definition

The universal quantification of predicate P(x) over domain U is the statement "P(x) for all values of x in the domain U" and is written $\forall x P(x)$ or $\forall x \in U P(x)$. When the domain is finite, universal quantification over the domain is equivalent to iterated *conjunction* (ands).

The existential quantification of predicate P(x) over domain U is the statement "There exists an element x in the domain U such that P(x)" and is written $\exists x P(x)$ for $\exists x \in U \ P(x)$. When the domain is finite, existential quantification over the domain is equivalent to iterated disjunction (ors).

An element for which P(x) = F is called a **counterexample** of $\forall x P(x)$.

An element for which P(x) = T is called a witness of $\exists x P(x)$.

Quantification logical equivalence

Statements involving predicates and quantifiers are logically equivalent means they have the same truth value no matter which predicates (domains and functions) are substituted in.

Quantifier version of De Morgan's laws: $|\neg \forall x P(x) \equiv \exists x (\neg P(x))|$

$$\neg \forall x P(x) \equiv \exists x (\neg P(x))$$

$$| \neg \exists x Q(x) \equiv \forall x (\neg Q(x))$$

Quantification examples finite domain

Examples of quantifications using V(x), N(x), Mystery(x):

True or False: $\exists x \ (V(x) \land N(x))$

True or False: $\forall x \ (V(x) \to N(x))$

True or **False**: $\exists x \ (\ N(x) \leftrightarrow Mystery(x)\)$

Rewrite $\neg \forall x \ (V(x) \oplus Mystery(x))$ into a logical equivalent statement.

Notice that these are examples where the predicates have *finite* domain. How would we evaluate quantifications where the domain may be infinite?

Rna rnalen basecount definitions

Recall the definitions: The set of RNA strands S is defined (recursively) by:

Basis Step: $A \in S, C \in S, U \in S, G \in S$

Recursive Step: If $s \in S$ and $b \in B$, then $sb \in S$

where sb is string concatenation.

The function rnalen that computes the length of RNA strands in S is defined recursively by:

 $rnalen: S \rightarrow \mathbb{Z}^+$

Basis Step: If $b \in B$ then rnalen(b) = 1

Recursive Step: If $s \in S$ and $b \in B$, then rnalen(sb) = 1 + rnalen(s)

The function basecount that computes the number of a given base b appearing in a RNA strand s is defined recursively by:

 $basecount: S \times B \rightarrow \mathbb{N}$ Basis Step: If $b_1 \in B, b_2 \in B$ $basecount(\ (b_1, b_2)\) = \begin{cases} 1 & \text{when } b_1 = b_2 \\ 0 & \text{when } b_1 \neq b_2 \end{cases}$ Recursive Step: If $s \in S, b_1 \in B, b_2 \in B$ $basecount(\ (sb_1, b_2)\) = \begin{cases} 1 + basecount(\ (s, b_2)\) & \text{when } b_1 = b_2 \\ basecount(\ (s, b_2)\) & \text{when } b_1 \neq b_2 \end{cases}$

Predicate rna example

Example predicates on S, the set of RNA strands (an infinite set)

 $H: S \to \{T, F\}$ where H(s) = T for all s.

Truth set of H is

 $F_{\mathtt{A}}:S \to \{T,F\}$ defined recursively by:

Basis step: $F_{\mathbf{A}}(\mathbf{A}) = T$, $F_{\mathbf{A}}(\mathbf{C}) = F_{\mathbf{A}}(\mathbf{G}) = F_{\mathbf{A}}(\mathbf{U}) = F$

Recursive step: If $s \in S$ and $b \in B$, then $F_{A}(sb) = F_{A}(s)$.

Example where F_{A} evaluates to T is _____

Example where F_{A} evaluates to F is _____

Predicates example rnalen basecount

Using functions to define predicates:

L with domain $S \times \mathbb{Z}^+$ is defined by, for $s \in S$ and $n \in \mathbb{Z}^+$,

$$L((s,n)) = \begin{cases} T & \text{if } rnalen(s) = n \\ F & \text{otherwise} \end{cases}$$

In other words, L((s,n)) means rnalen(s) = n

BC with domain $S \times B \times \mathbb{N}$ is defined by, for $s \in S$ and $b \in B$ and $n \in \mathbb{N}$,

$$BC((s,b,n)) = \begin{cases} T & \text{if } basecount((s,b)) = n \\ F & \text{otherwise} \end{cases}$$

In other words, $BC(\ (s,b,n)\)$ means $basecount(\ (s,b)\)=n$

Example where L evaluates to T: _____ Why?

Example where BC evaluates to T: Why?

Example where L evaluates to F: _____ Why?

Example where BC evaluates to F: Why?

$$\exists t \ BC(t) \qquad \exists (s,b,n) \in S \times B \times \mathbb{N} \ (basecount(\ (s,b)\) = n)$$

In English:

Witness that proves this existential quantification is true:

$$\forall t \ BC(t) \qquad \forall (s, b, n) \in S \times B \times \mathbb{N} \ (basecount(\ (s, b)\) = n)$$

In English:

Counterexample that proves this universal quantification is false:

Predicates projecting example rna basecount

New predicates from old

1. Define the **new** predicate with domain $S \times B$ and rule

$$basecount((s,b)) = 3$$

Example domain element where predicate is T:

2. Define the **new** predicate with domain $S \times \mathbb{N}$ and rule

$$basecount((s, A)) = n$$

Example domain element where predicate is T:

3. Define the **new** predicate with domain $S \times B$ and rule

$$\exists n \in \mathbb{N} \ (basecount(\ (s,b)\) = n)$$

Example domain element where predicate is T:

4. Define the **new** predicate with domain S and rule

$$\forall b \in B \ (basecount(\ (s,b)\)=1)$$

Example domain element where predicate is T:

Predicate notation

Notation: for a predicate P with domain $X_1 \times \cdots \times X_n$ and a n-tuple (x_1, \ldots, x_n) with each $x_i \in X$, we can write $P(x_1, \ldots, x_n)$ to mean $P((x_1, \ldots, x_n))$.

Nested quantifiers

Nested quantifiers

$$\forall s \in S \ \forall b \in B \ \forall n \in \mathbb{N} \ (basecount((s,b)) = n)$$

In English:

Counterexample that proves this universal quantification is false:

$$\forall n \in \mathbb{N} \ \forall s \in S \ \forall b \in B \ (basecount(\ (s,b)\) = n)$$

In English:

Counterexample that proves this universal quantification is false:

Compound proposition definitions

Proposition: Declarative sentence that is true or false (not both).

Propositional variable: Variable that represents a proposition.

Compound proposition: New proposition formed from existing propositions (potentially) using logical operators. *Note*: A propositional variable is one example of a compound proposition.

Truth table: Table with one row for each of the possible combinations of truth values of the input and an additional column that shows the truth value of the result of the operation corresponding to a particular row.

Logical equivalence

Logical equivalence: Two compound propositions are logically equivalent means that they have the same truth values for all settings of truth values to their propositional variables.

Tautology: A compound proposition that evaluates to true for all settings of truth values to its propositional variables; it is abbreviated T.

Contradiction: A compound proposition that evaluates to false for all settings of truth values to its propositional variables; it is abbreviated F.

Contingency: A compound proposition that is neither a tautology nor a contradiction.

Tautology contradiction contingency examples

 $p \wedge p$

 $p\oplus p$

 $p \lor p$

 $p \vee \neg p$

 $p \land \neg p$

Logical equivalence extra example

Extra Example: Which of the compound propositions in the table below are logically equivalent?

Inp	out	Output				
p	q	$\neg (p \land \neg q)$	$\neg (\neg p \lor \neg q)$	$(\neg p \lor q)$	$(\neg q \lor \neg p)$	$(p \land q)$
\overline{T}	T					
T	F					
F	T					
F	F					

Algorithm definition

New! An algorithm is a finite sequence of precise instructions for solving a problem.

Algorithms can be expressed in English or in more formalized descriptions like pseudocode or fully executable programs.

Sometimes, we can define algorithms whose output matches the rule for a function we already care about. Consider the (integer) logarithm function

$$logb: \{b \in \mathbb{Z} \mid b > 1\} \times \mathbb{Z}^+ \rightarrow \mathbb{N}$$

defined by

 $logb((b,n)) = greatest integer y so that b^y is less than or equal to n$

Calculating integer part of base b logarithm

```
procedure logb(b,n): positive integers with b>1)

i:=0

while n>b-1

i:=i+1

n:=n div b

return i {i holds the integer part of the base b logarithm of n}
```

Trace this algorithm with inputs b=3 and n=17

	b	n	i	n > b - 1?
Initial value	3	17		
After 1 iteration				
After 2 iterations				
After 3 iterations				

Compare: does the output match the rule for the (integer) logarithm function?

Fixed width definition

Definition For b an integer greater than 1, w a positive integer, and n a nonnegative integer _____, the base b fixed-width w expansion of n is

$$(a_{w-1}\cdots a_1a_0)_{b,w}$$

where $a_0, a_1, \ldots, a_{w-1}$ are nonnegative integers less than b and

$$n = \sum_{i=0}^{w-1} a_i b^i$$

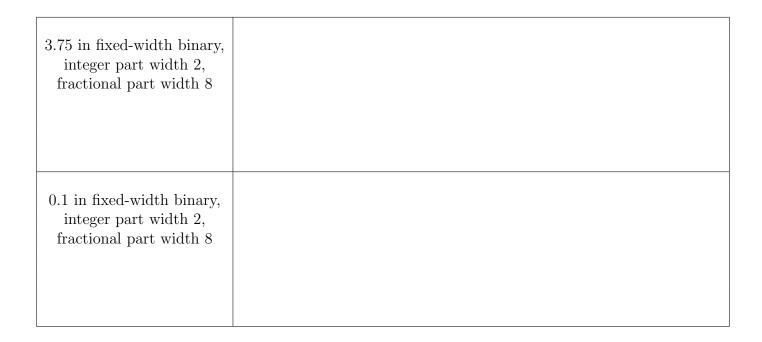

Fixed width example

Decimal	Binary	Binary fixed-width 10	Binary fixed-width 7	Binary fixed-width 4
b = 10	b=2	b = 2, w = 10	b = 2, w = 7	b = 2, w = 4
$(20)_{10}$				

Fixed width fractional definition

Definition For b an integer greater than 1, w a positive integer, w' a positive integer, and x a real number the base b fixed-width expansion of x with integer part width w and fractional part width w' is $(a_{w-1} \cdots a_1 a_0.c_1 \cdots c_{w'})_{b,w,w'}$ where $a_0, a_1, \ldots, a_{w-1}, c_1, \ldots, c_{w'}$ are nonnegative integers less than b and

$$x \ge \sum_{i=0}^{w-1} a_i b^i + \sum_{j=1}^{w'} c_j b^{-j}$$
 and $x < \sum_{i=0}^{w-1} a_i b^i + \sum_{j=1}^{w'} c_j b^{-j} + b^{-w'}$

Note: Java uses floating point, not fixed width representation, but similar rounding errors appear in both.

Negative int expansions

Representing negative integers in binary: Fix a positive integer width for the representation w, w > 1.

	To represent a positive integer n	To represent a negative integer $-n$
Sign-magnitude	$[0a_{w-2}\cdots a_0]_{s,w}$, where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $n=17, w=7$:	$[1a_{w-2}\cdots a_0]_{s,w}$, where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $-n=-17, w=7$:
2s complement	$[0a_{w-2}\cdots a_0]_{2c,w}$, where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $n=17, w=7$:	$[1a_{w-2}\cdots a_0]_{2c,w}$, where $2^{w-1}-n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $-n=-17, w=7$:

Calculating 2s complement

For positive integer n, to represent -n in 2s complement with width w,

- Calculate $2^{w-1} n$, convert result to binary fixed-width w 1, pad with leading 1, or
- Express -n as a sum of powers of 2, where the leftmost 2^{w-1} is negative weight, or
- Convert n to binary fixed-width w, flip bits, add 1 (ignore overflow)

Challenge: use definitions to explain why each of these approaches works.

Representing zero

Representing 0:

So far, we have representations for positive and negative integers. What about 0?

	To represent a non-negative integer n	To represent a non-positive integer $-n$
Sign-magnitude	$[0a_{w-2}\cdots a_0]_{s,w}$, where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $n=0, \ w=7$:	$[1a_{w-2}\cdots a_0]_{s,w}$, where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $-n=0, w=7$:
2s complement	$[0a_{w-2}\cdots a_0]_{2c,w}$, where $n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $n=0, w=7$:	$[1a_{w-2}\cdots a_0]_{2c,w}$, where $2^{w-1}-n=(a_{w-2}\cdots a_0)_{2,w-1}$ Example $-n=0, w=7$:

Netflix intro

What data should we encode about each Netflix account holder to help us make effective recommendations?

In machine learning, clustering can be used to group similar data for prediction and recommendation. For example, each Netflix user's viewing history can be represented as a n-tuple indicating their preferences about movies in the database, where n is the number of movies in the database. People with similar tastes in movies can then be clustered to provide recommendations of movies for one another. Mathematically, clustering is based on a notion of distance between pairs of n-tuples.

Data types

Term	Examples:	
	(add additional	examples from class)
set	$7 \in \{43, 7, 9\}$	$2 \notin \{43, 7, 9\}$
unordered collection of elements		
repetition doesn't matter		
Equal sets agree on membership of all elements		
n-tuple		
ordered sequence of elements with n "slots" $(n > 0)$		
repetition matters, fixed length		
Equal n-tuples have corresponding components equal		

string

ordered finite sequence of elements each from specified set (called the alphabet over which the string is defined) repetition matters, arbitrary finite length Equal strings have same length and corresponding characters equal

$Special\ cases:$

When n = 2, the 2-tuple is called an **ordered pair**.

A string of length 0 is called the **empty string** and is denoted λ .

A set with no elements is called the **empty set** and is denoted $\{\}$ or \emptyset .

Set operations

To define a set we can use the roster method, set builder notation, a recursive definition, and also we can apply a set operation to other sets.

New! Cartesian product of sets and set-wise concatenation of sets of strings

Definition: Let X and Y be sets. The **Cartesian product** of X and Y, denoted $X \times Y$, is the set of all ordered pairs (x, y) where $x \in X$ and $y \in Y$

$$X \times Y = \{(x, y) \mid x \in X \text{ and } y \in Y\}$$

Conventions: (1) Cartesian products can be chained together to result in sets of n-tuples and (2) When we form the Cartesian product of a set with itself $X \times X$ we can denote that set as X^2 , or X^n for the Cartesian product of a set with itself n times for a positive integer n.

Definition: Let X and Y be sets of strings over the same alphabet. The **set-wise concatenation** of X and Y, denoted $X \circ Y$, is the set of all results of string concatenation xy where $x \in X$ and $y \in Y$

$$X \circ Y = \{xy \mid x \in X \text{ and } y \in Y\}$$

Pro-tip: the meaning of writing one element next to another like xy depends on the data-types of x and y. When x and y are strings, the convention is that xy is the result of string concatenation. When x and y are numbers, the convention is that xy is the result of multiplication. This is (one of the many reasons) why is it very important to declare the data-type of variables before we use them.

Fill in the missing entries in the table:

Set	Example elements in this set and their data type:
B	A C G U
	(A,C) (U,U)
$B \times \{-1, 0, 1\}$	
$\{-1,0,1\} \times B$	
	(0, 0, 0)
$\{\mathtt{A},\mathtt{C},\mathtt{G},\mathtt{U}\}\circ\{\mathtt{A},\mathtt{C},\mathtt{G},\mathtt{U}\}$	
	GGGG

Defining functions

New! Defining functions A function is defined by its (1) domain, (2) codomain, and (3) rule assigning each element in the domain exactly one element in the codomain.

The domain and codomain are nonempty sets.

The rule can be depicted as a table, formula, piecewise definition, or English description.

The notation is

"Let the function FUNCTION-NAME: DOMAIN \to CODOMAIN be given by FUNCTION-NAME(x) = ... for every $x \in DOMAIN$ ".

or

"Consider the function FUNCTION-NAME: DOMAIN \rightarrow CODOMAIN defined as FUNCTION-NAME(x) = ... for every $x \in DOMAIN$ ".

Example: The absolute value function

Domain

Codomain

Rule

Defining functions recursively

When the domain of a function is a recursively defined set, the rule assigning images to domain elements (outputs) can also be defined recursively.

Recall: The set of RNA strands S is defined (recursively) by:

Basis Step: $A \in S, C \in S, U \in S, G \in S$ Recursive Step: If $s \in S$ and $b \in B$, then $sb \in S$

where sb is string concatenation.

Definition (Of a function, recursively) A function rnalen that computes the length of RNA strands in S is defined by:

Basis Step: If $b \in B$ then rnalen(s) = 1Recursive Step: If $s \in S$ and $b \in B$, then rnalen(sb) = 1 + rnalen(s)

The domain of rnalen is

The codomain of rnalen is

Example function application:

$$rnalen(ACU) =$$

Example: A function basecount that computes the number of a given base b appearing in a RNA strand s is defined recursively:
